

Backend Quality Analyst (API & Automation)

Sundial Technologies · Hyderabad (hybrid, 3 days on site) · Full-time · 3–5 years

About us

Sundial builds subscription billing infrastructure for Indian SaaS companies. Invoicing, proration, dunning, tax, and the reconciliation that sits behind all of it. About 240 customers, and roughly ₹900 crore of billing runs through the platform each year. Engineering is 34 people across six squads. We have three testers and are hiring a fourth.

The role

You will own testing for two of our backend services, most likely invoicing and the webhooks service, working inside a squad of five engineers. It is a hands-on API testing job. There is almost no UI. Most of your day is reading a story, working out how it breaks, writing the tests, and chasing down the failures that come out of the nightly run. You report to the QA Lead, who owns the framework and the pipeline, so you are inheriting both rather than building them. Compensation is ₹9,00,000 – ₹14,00,000 per annum depending on experience.

What you will actually do

- Write and maintain the automated API tests for your services. Our suite is Python with pytest and requests, around 900 tests, and you will be adding to it every sprint.
- Turn a user story into a set of test cases before the code is written, including the cases nobody thought about: the empty list, the duplicate request, the currency with no decimal places, the customer who cancels mid-cycle.
- Check the database, not just the response body. An API can return 200 and still write the wrong ledger entry, and on a billing platform that is the failure that costs money. You will be writing SQL against Postgres daily.
- Investigate a failure far enough that the developer gets something useful. The request, the response, the relevant log lines, and a narrowed repro, rather than a screenshot and a shrug.
- Keep the nightly run green. Some of what you find will be real bugs and some will be flaky tests, and telling those two apart quickly is most of the job.
- Run and sign off the regression pass before each fortnightly release.
- Speak up in refinement when a story cannot be tested as written. This is expected, not tolerated.
- Raise and track defects in Jira, retest the fixes, and close the loop.

What we are looking for

- You have written and maintained an automated API test suite that other people relied on, and can talk through how you decided what to automate and what to leave manual.
- You have designed test cases from a written requirement, and can give an example of an edge case you thought of that the team had missed.
- You verify data at the database level and are comfortable writing your own SQL joins to do it.
- You have found a bug that would have caused real damage if it had shipped, and can walk us through how you found it.
- You have dealt with a flaky test: worked out why it was flaky and either fixed it or made the call to quarantine it.
- You can read an application log and narrow a failure before handing it over.

- You have worked in two-week sprints with developers, not in a separate testing phase after the fact.

Nice to have

- Billing, payments, fintech or accounting domain exposure
- Contract testing, or any experience with Pact
- Basic load testing with JMeter or k6
- Running services locally with Docker Compose
- Some experience with GitHub Actions, though our lead owns the pipeline

What this job is not

You will not be building the automation framework, owning the CI pipeline, managing testers, or setting QA strategy for the company. Those sit with the QA Lead and the Head of Engineering. If you are looking for that step up, this is not the right role yet, and we would rather say so now.

Benefits

Health cover for you and immediate family, 24 days leave, a learning budget of ■40,000 a year, and hybrid working with three days in our Gachibowli office.

To apply, send your CV to careers@sundialtech.example. We reply to every application within a week.
